

Data Crow

Creating Reports

*Written by Robert Jan van der Waals | August 25, 2014 |
Version 1.2 | Based on Data Crow 4.0.7 (and higher)*

Introduction

Data Crow allows users to add their own reports or to modify the existing reports. The reports are created with the Jaspersoft Studio software. This software is free for download.

Prerequisites

- For creating report the Jaspersoft studio software needs to be installed. Download the software from: <https://community.jaspersoft.com/project/jaspersoft-studio>. Download the latest version available.
- You need Data Crow version 4.0.7 or higher.
- You need to have the Java installed (version 7 or higher). This can be downloaded from the Oracle site: <https://www.oracle.com/java/>. This is also a requirement for running Data Crow.

The report process

Report templates

Data Crow uses compiled reports from Jaspersoft (.jasper file). These are placed in the reports folder of the Data Crow installation folder. When the software is upgraded the user will be asked whether he/she wants copy the reports over to the reports folder of the installation to the user folder. When you want to test your created or modified reports, copy them to the reports folder of the **user folder**.

Each time the report dialog is opened, Data Crow scans the reports folder of the **user folder** for existing .jasper reports files. As Data Crow consists of multiple modules, the reports need to be placed in the reports folder of the module. The folder structure for reports for a particular module is as follows: *<user folder>/Reports/<module name>*

Example for Microsoft Windows:

```
D:\Data Crow Data\Reports\Software  
D:\Data Crow Data\Reports\Movie
```

Example for Linux:

```
/Home/Data Crow Data/Reports/Software
```

Note: it might be the case that your user folder also holds sub directories called PDF and HTML. These are leftovers from older Data Crow versions. These are no longer in use and can be safely removed. The same goes for the files contained within.

Report creation

When you run a report from Data Crow (Tools > Create Report) Data Crow does three things:

- 1) Data Crow creates an XML export of the selected items.
- 2) Data Crow fills the .jasper report file with the XML data.
- 3) And as a last step the filled report is saved in the selected target format (RTF, PDF or HTML).

The most important thing to note is that Data Crow uses XML extracts for creating the reports rather than accessing the database directly. We will use the XML in the next chapter to design a new (or modify an existing) report.

Secondly, it is no longer required for the reporting process to export the images. Jaspersoft does this automatically in case needed, such as is the case for the HTML reports.

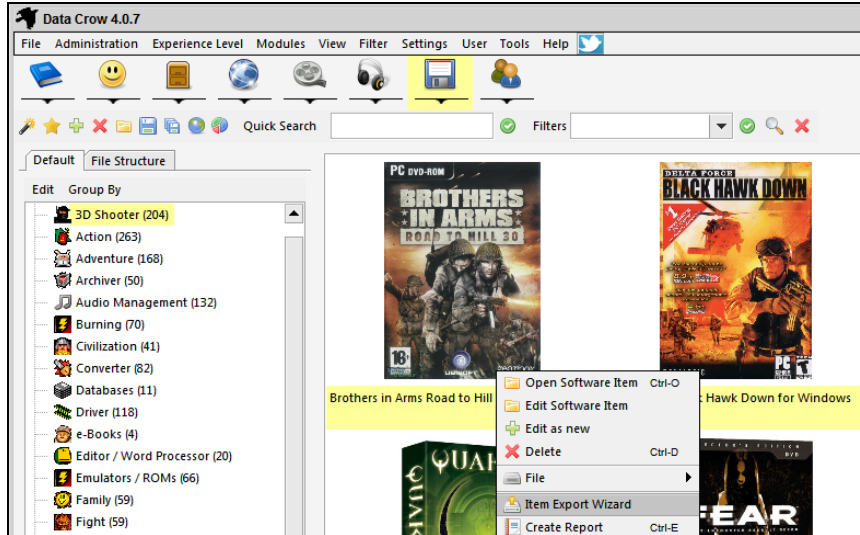

Creating a new reports

Let's create a new report!

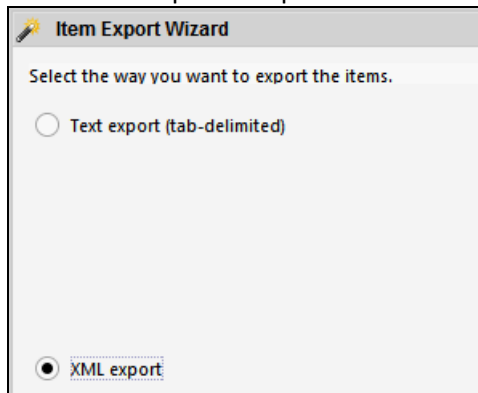

Create an XML export

First, we need to have an example XML file so we can use this to design our report.

1. Start Data Crow
2. Select the module for which you want to create a report
3. Select one or more items in the overview, right-click and select *Item Export Wizard*:

4. Select XML export and press *Next*:

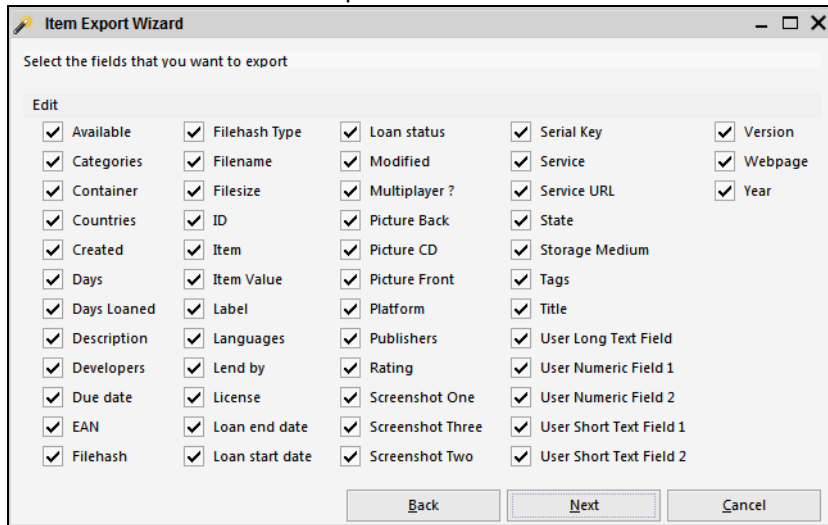

5. Select the target file and press *Next*:

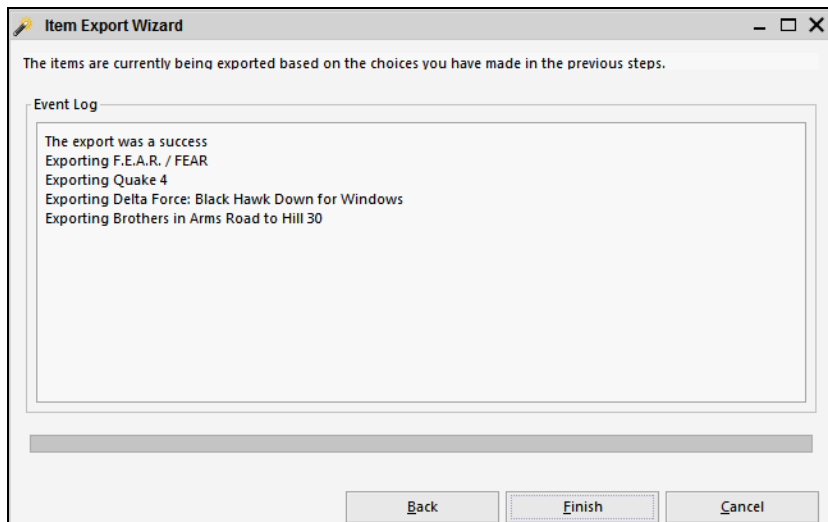

Leave the images and text settings on default

6. Leave all fields selected and press *Next*:

7. The XML is created:

Note that we will only use this XML as an example for creating our new report. Data Crow will create the XML extract automatically when you run the report from within Data Crow (Tools > Create Report). It's important that you selected items which hold the most information as well as a couple of items with very limited information. This is always good for testing the report.

Set up the XML as Report Source

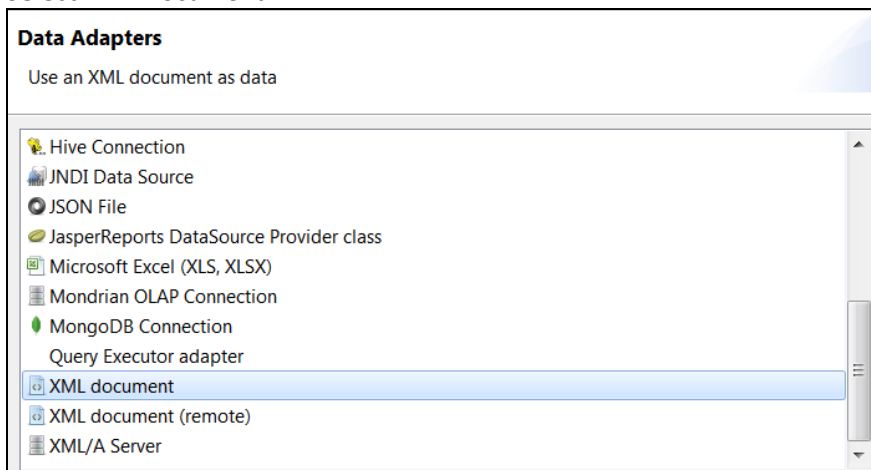

Next, start Jaspersoft Studio. On a first start you will be asked to select a workspace location. Pick any location that you want. Once started close out of any of the welcome screens until you are in the actual work area.

First thing we need to do is to set up the XML file we exported as a *Data Adapter*. Data adapters are used to fill reports with data. Select the *Repository Explorer* tab and right-click on the *Data Adapters*. From the right-click menu, select *Create Data Adapter*.

Select *XML Document*:

Press *Next* to further configure the XML data adapter.

Data Adapter
XML document

Name: Test XML

File: C:\Users\RJ\Documents\test.xml

Enable namespaces support
 Use the report Xpath expression when filling the report
 Create data source using this expression :

Select Expression :

Date pattern :

Number pattern :

Locale / Time zone

Locale : Default (Nederlands (Nederland))

Time zone : Default (Europe/Berlin)

Fill at least the following fields (other fields are optional and explained in the documentation of JasperSoft Studio):

- Name: enter any name you want, recognizable to yourself.
- File: select the XML export as created by Data Crow. In my case this was text.xml. Note that for running the report by Data Crow this file will not be used, this is only for designing the report.
- Tick the “Use the report Xpath expression when filling the report”. This is very important as you otherwise will end up with an empty report for your test runs.

Press *Test* to test your set up.

Press *Finish* to end the data adapter creation.

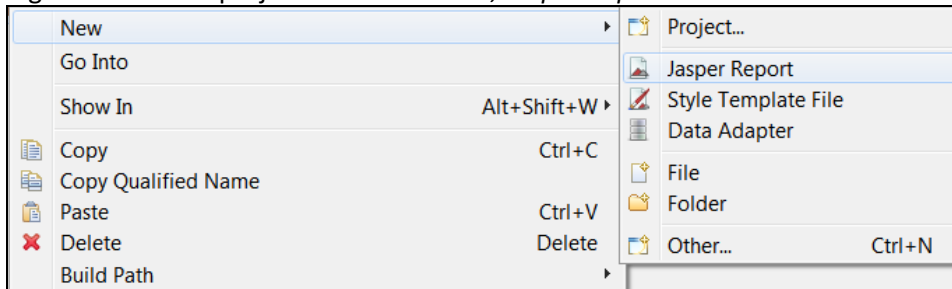

Create a blank report

So we now have an XML file which is set up as a data adapter in your Jaspersoft environment. Next logical step is to create a new report, using the data adapter as input.

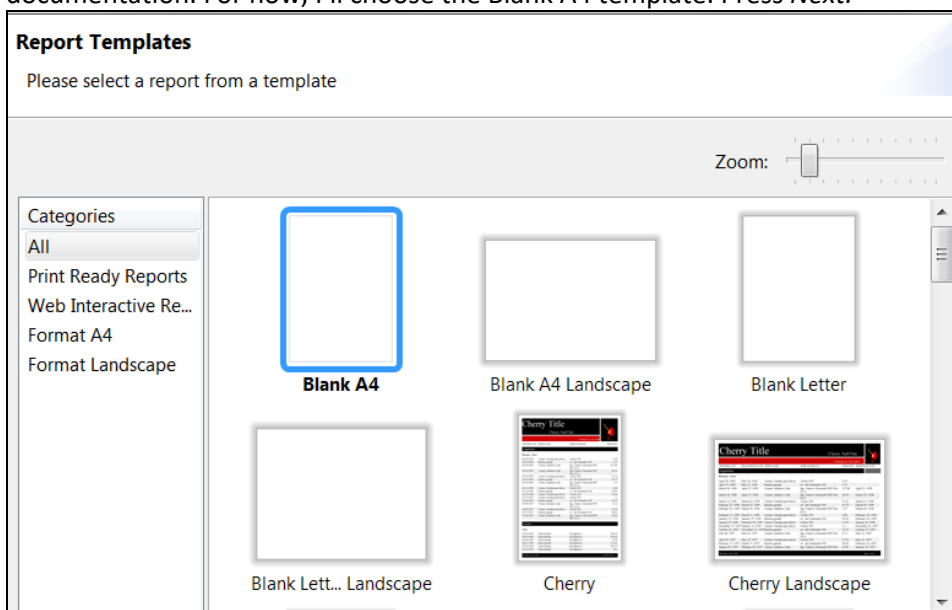

Navigate to the *Project Explorer*. By default this will hold a project named *MyReports*. You are free to use any other project name you want to, it's not important for the Data Crow reports.

Right-click on the project and select *New, Jasper Report*.

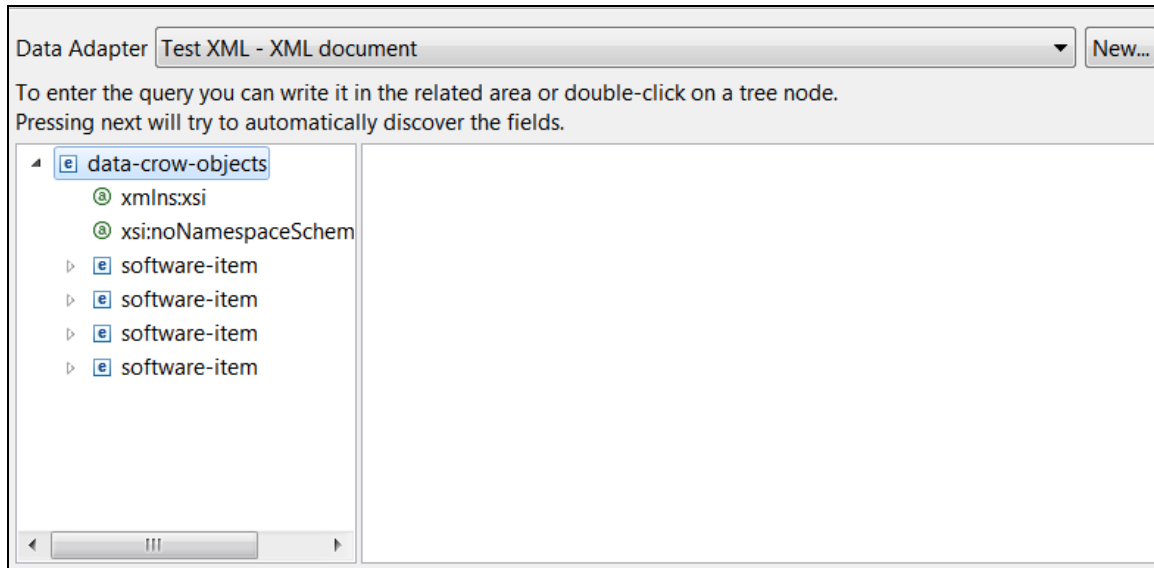

Now you can select a *Report Template*. For Data Crow reports you can choose any report template you want. For more details on these templates I refer you to the Jaspersoft Studio documentation. For now, I'll choose the Blank A4 template. Press *Next*.

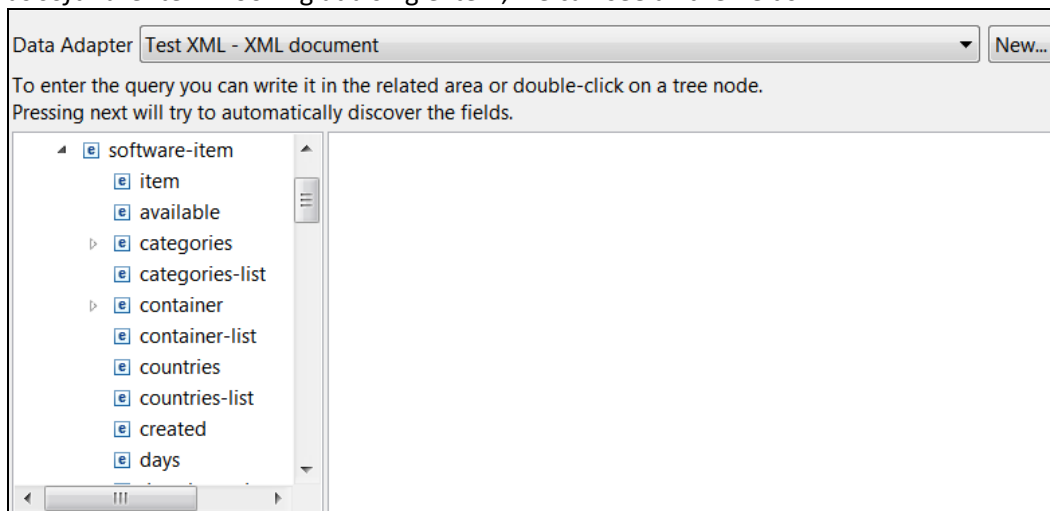

Next Jaspersoft Studio will ask you to name the report so that it can be saved into your project. Give it a name that will make sense; the name of the report file is shown in the Data Crow report selection. For this example I'll call this report *Test*. Press *Next* to continue to the next step.

File name: Test.jrxml

Now, we are in step where we will link the data adapter to the report. This will allow the report to find the fields available and fill them with information when running the report.

- Select the Data Adapter from the dropdown. In my case it is called Test XML.
- In the field below the structure of the XML file is shown. Now we need to define how Jaspersoft Studio has to use the XML information. For the example you can see I have exported software items. A total number 4 items are present, each item is represented as *software-item*. Looking at a single item, we can see all the fields:

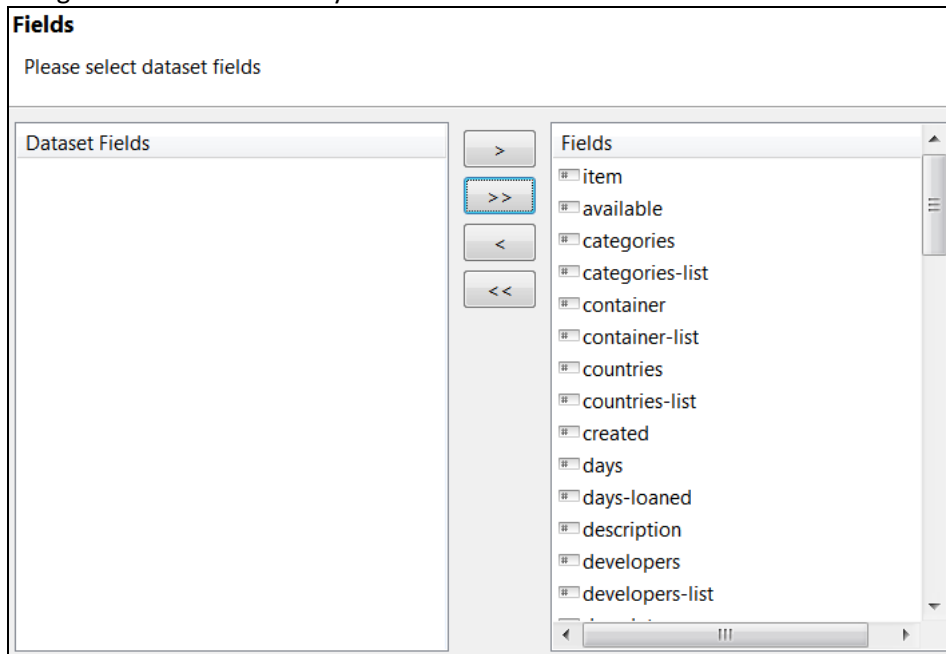

- Double click on the node that holds all the fields. This makes all items available in the report.

Note that for XML exports from other modules you will see for example Movie, Book, Music Album, etcetera instead of *software-item*. The steps to follow are exactly the same. Press *Next*.

- In the next step you'll have to choose which fields to include in the report. If no fields are listed or this step is skipped it means you have made a mistake in the previous step. I have selected all fields by pressing on the >> button. I recommend adding all fields as this gives the most flexibility.

- At this point you can choose to *Finish* the wizard. Alternatively you can continue by pressing *Next* which brings you to the option to set up grouping. Grouping however is not covered in this guide; I'll have to refer you to the Jaspersoft Studio documentation. It is supported by Data Crow, so no worries there.

So now we have a blank report with a configured data adapter.

Design tips & Tricks

For full documentation on how to design your report in the JasperSoft Studio software you are referred to the documentation available from the JasperSoft site:

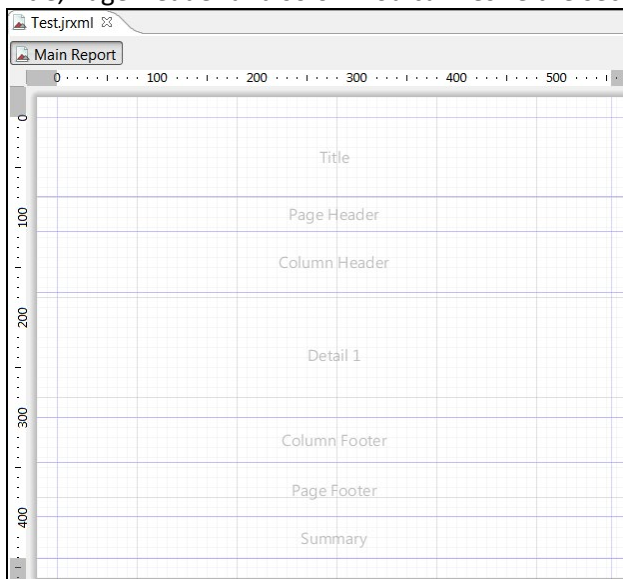

<https://community.jaspersoft.com/project/jaspersoft-studio>

There are manuals as well as Wikis available.

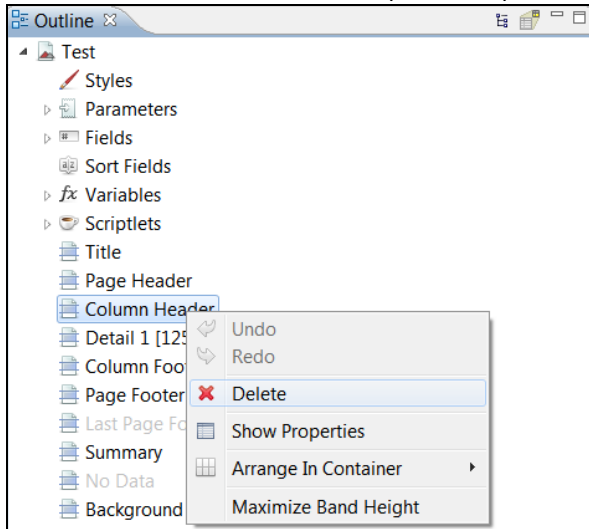

To help you get started, I'll explain some of the basics.

Report Layout

In the centre of the screen you'll find the report itself. You can see the various sections, such as Title, Page Header and so on. You can resize the sections with the mouse.

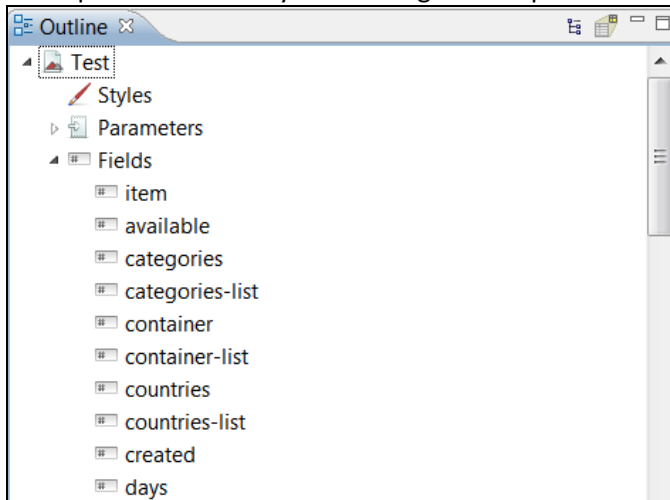

These sections can be removed (or added) from within the Outline section:

Adding fields

All the fields as part of the XML data adapter can be found in the outline section of the workspace. From here you can drag and drop fields onto the report:

Multi-reference fields

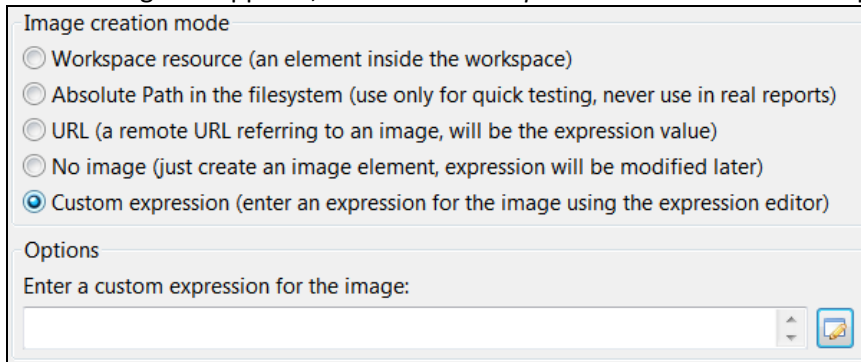

Note that for each multi-reference field I have added a *fieldname-list* field (see above for examples, such as *categories-list*). This contains the comma separated values. If you want to iterate over the individual items instead you'll have to add a *List* element.

Image fields (pictures)

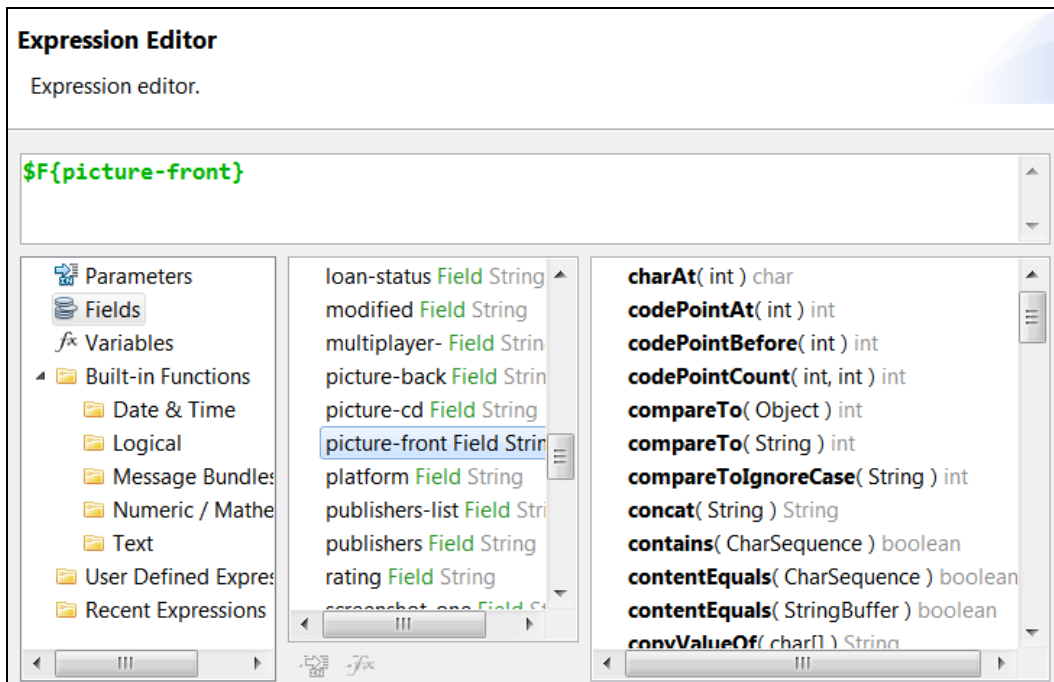

Optionally you can also choose to first add a specific element onto the report and then specify which value to use. Let's add an image for example. On the right hand side of the screen you'll find a section called palette. Here you find all field types available. Select Image and drag and drop this onto the report.

In the dialog that appears, select *Custom expression*. This enables the Options field.

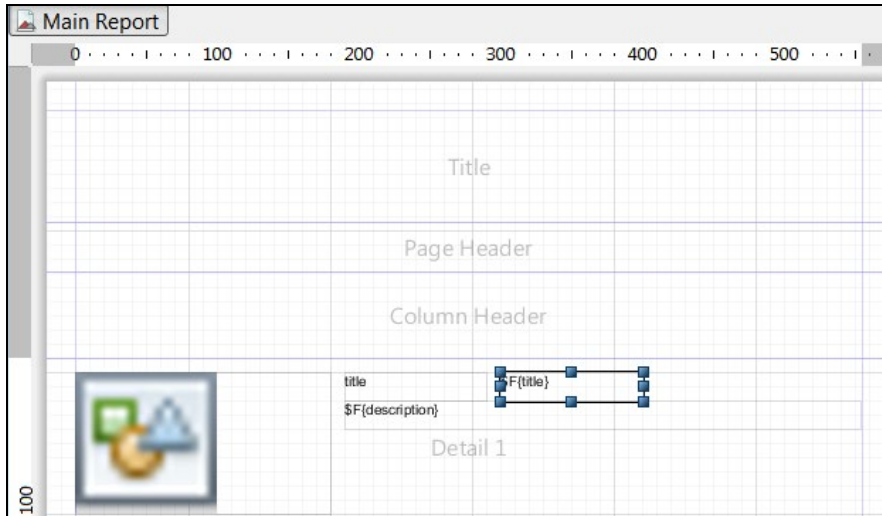

Press the  button.

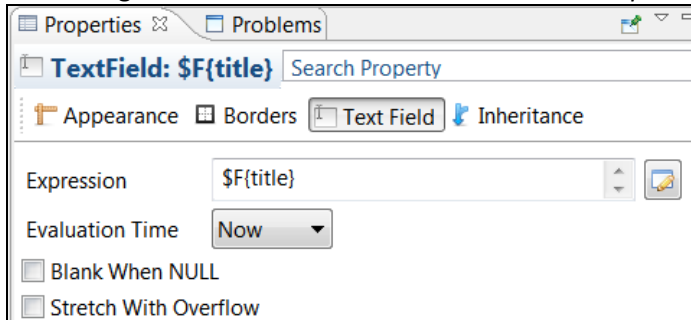

By default the Fields are all shown. Select the picture field you want to add and double-click it. I have select the picture-front field.

Empty field content

Jaspersoft will print NULL in case the field is empty. I prefer to have the field show nothing in case a field is empty. This can be done through the properties of the field. Select the field by clicking on it in the *Main Report* view. In the example below I have selected the Title field.

Next navigate to the *Tools* section and select the *Properties* (selected by default).

Check the option *Blank When NULL*.

There are advanced options available, such as hiding the field completely when it is empty. This is not covered in this guide.

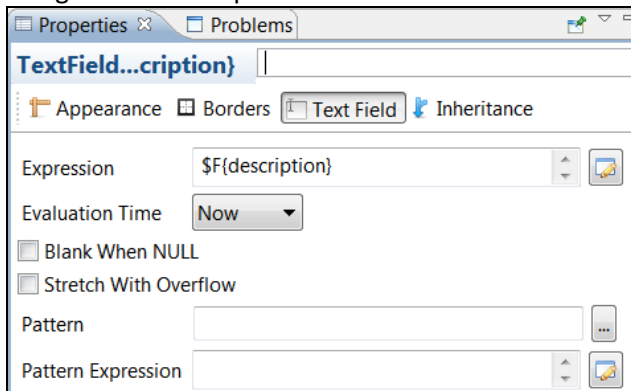

Long text fields / field overflow

When you add a field to the report, you can size the field. The main problem with sizing fields is that you need to anticipate the actual content size. In case you add a description field for example you need to make sure the whole description text is shown in the report. This can be configured through the properties of the field.

In the example below I have added a description field. It won't fit more than one line of text, so it will definitely be too small:

Let's change the properties of this field. Click on the field (as done in the above example). Now navigate to the Properties section. Select *Text Field*.

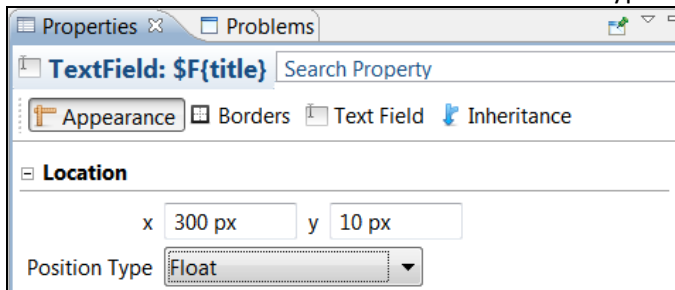

Check the box *Stretch With Overflow*. It does just that; whenever the content is too large, the field will be stretched, making all of its content visible.

Field positioning

Any field added to the report is automatically aligned, related to the top. This can be quite useful if you want your field to remain at the same place at all times; when the report is stretched the position of the field remain at the same relative distance of the top of the report section.

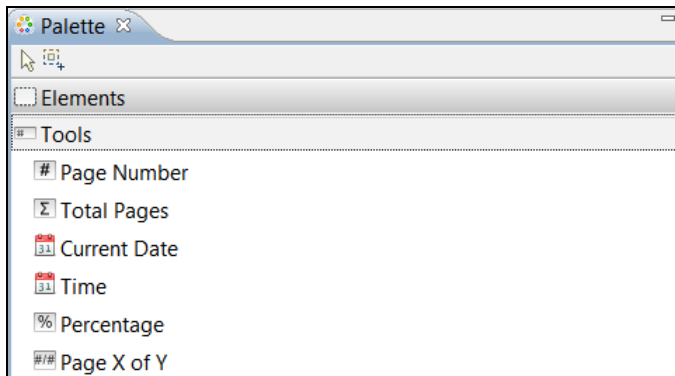

This problematic when you have placed the field below a text field (see above) which *Stretches With Overflow*. The field will be placed on top of the stretched field as it positions itself relative to the top of the report section, not relative to the field above.

To accommodate for this set this field to Position Type *Float* instead:

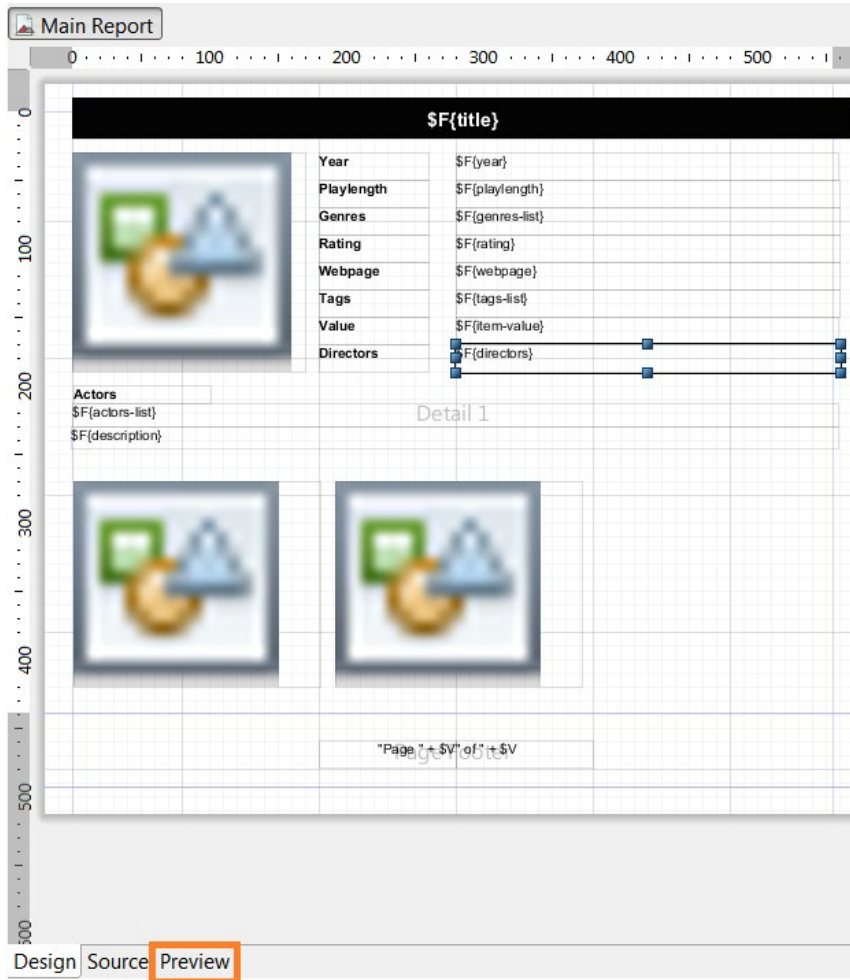

Other fields

There are many field types available to display the source content (the XML information). There are also fields available such as the page number. These fields can be found in the Palette section:

Report Preview

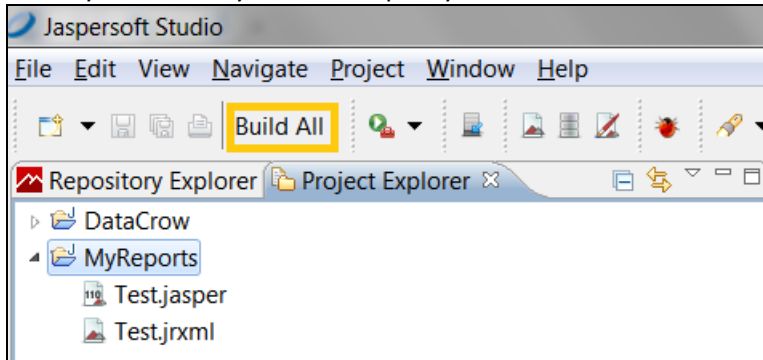

At any time during the design process you can do a preview of the report. Click on the preview button, as shown below:

By doing a preview you get to see what the report looks like to the end user. Also, the report is checked for errors.

Compiling and Deploying the Report

When you are ready with the report you can build it and make it available to Data Crow.

Press the *Build All* button. This creates a .jasper file.

All you need to do now is to copy the .jasper file to the Data Crow reports folder of the user folder. The report folder structure is explained in the Report Process chapter;

`<user folder>/Reports/<module name>`

You do not need to restart Data Crow to run the report. Simply re-open the Report Dialog. For this example I have copied the Test.jasper file to the reports folder of my user folder:

`C:\Users\RJ\Data\Development\dc data\reports\software`

Next I start the *Create Report* tool:

I select the Test report I have just created:

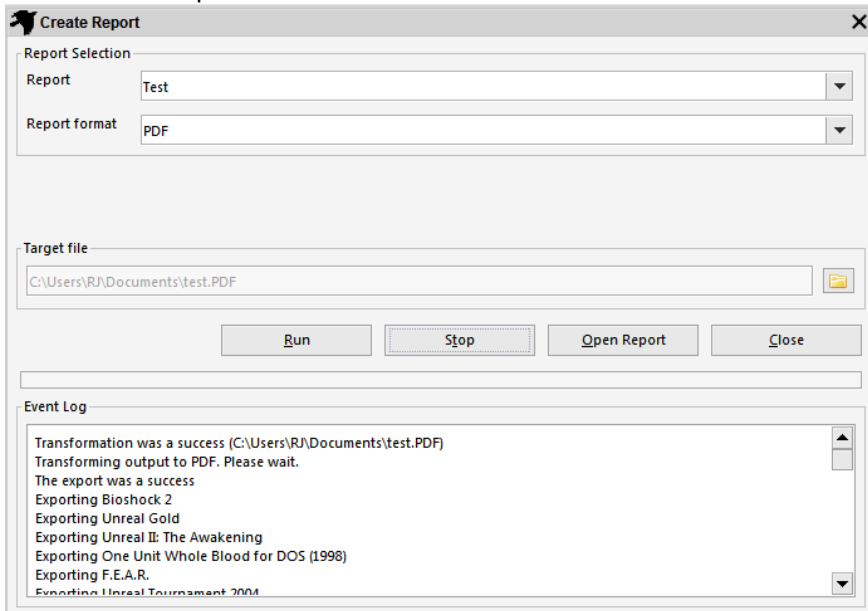

And I select the *Report Type*:

And of course the target file.

To create the report I select *Run*.

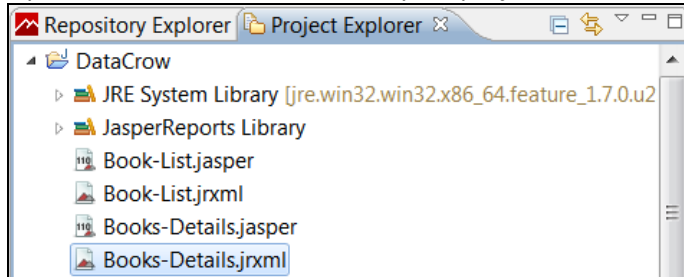

The transformation was successful, allowing me to open the Report.

Modifying existing reports

The existing reports can be modified. Not the .jasper files as these are compiled versions. For changing the reports you need the JRXML files. These are supplied with the installation and are located in the Reports folder of your Data Crow installation. Copy these to your JasperSoft Studio project folder (within the Workspace folder you have selected).

1. Create an XML Data Adapter as explained previously.
2. Open the JRXML file from within your project.

3. Open the Source tab:

Change the name of the *defaultdataadapter* to the name of the Data Adapter you have created. It needs to be the exact name; copy & paste is the best way to do this.

You are now ready to modify the report!
